

APPLICATION FOR UNITED STATES LETTERS PATENT

INVENTOR(S): Hiroshi YOSHINO

INVENTION: INK JET APPARATUS AND WASTE  
LIQUID ABSORBING METHOD

S P E C I F I C A T I O N

## BACKGROUND OF THE INVENTION

### FIELD OF THE INVENTION

5       The present invention relates generally to an ink jet apparatus and a waste liquid absorbing method each of which assure that an image having a high quality can be obtained on a printing medium. More particularly, the present invention relates to an ink  
10   jet apparatus for ejecting on the printing medium liquid having a function of undissolving a coloring material in ink prior to ejection of the ink.

      The present invention is applicable to all kinds of instruments for which a printing medium such as a  
15   sheet of paper, unwoven fabric, a sheet of OHP film or the like is used. The applicable instrument is typically exemplified by an office machine and a mass production machine such as a printer, a copying machine, a facsimile or the like.

20       An ink jet printing method is utilized for a printer, a copying machine, a facsimile or the like for the reasons that a low level of noisy sound is generated, the ink jet method is practiced at a low running cost, an apparatus is easily designed with  
25   small dimensions, and an image is easily formed by using colored inks.

However, the ink jet printing system has the following specific problems to be solved.

(1) Since a printing operation is performed by ejecting ink droplets from an ink jet head to a sheet of paper, a sheet of OHP film or a similar printing medium, fine ink mist other than the ejected main ink droplets or ink mist ejected to the printing medium rebounds to an ink jet head, causing the ink mist to adhere to an ink ejecting port surface until a large quantity of ink mist get together around the ink ejecting port. In addition, when paper powder or a similar foreign material adheres to the fine mist, ink ejection is obstructed, causing ink droplets to be ejected in an unexpected direction. In an extreme case, ink droplets can not be ejected.

(2) Unless the ink jet head is continuously ejected for a long time inclusive of non-printing time, ink in the nozzle is dried due to vaporization, resulting in the nozzle being clogged with ink having increased viscosity or solidified ink. Thus, there arises a malfunction that ink is ejected in the warped state or no ink ejection is effected.

The ink jet apparatus is generally equipped with recovering means as means for solving the problems as mentioned in the paragraph (1) and the paragraph (2). Specifically, when no printing operation is performed,

an ink jet head is capped with capping means for the purpose of preventing ink in a nozzle of the ink jet head from being vaporized and dried, resulting in the ink having increased viscosity or adherence to the nozzle. In the case that incorrect ejection is effected due to increased viscosity or adherence, foreign material which can not be removed by a blade adhere to the ink ejecting port surface, ink having increased viscosity in the nozzle is discharged by operating a suction pump connected to the cap so as to conduct recovering treatment for recovering normal ejection. Here, the discharged ink is sucked in a waste ink absorbing substance disposed in a housing of the apparatus via piping extending downstream of the suction pump.

A capacity of the waste ink absorbing substance is determined depending on the number of times of incorrect printings, the number of times of recovering operations, a quantity of ink squeezed or sucked every recovering operation or a quantity of ink mist discharged from the ink jet head, it is recommendable from the viewpoint of the whole structure of the apparatus that the waste ink absorbing substance is compactly designed to have a small capacity because it is expected that the position where it is disposed is not restricted, and moreover, it is fabricated at a

low cost. However, if a capacity of the waste ink absorbing substance is set to a quantity originally required by the apparatus, there arises an inconvenience of maintenance that the waste ink absorbing substance is periodically replaced with a new one. On the contrary, when a waste ink absorbing substance having a required capacity is disposed on the apparatus, the waste ink absorbing substance is relatively enlarged, causing it to be fabricated at an increased cost, and moreover, the housing of the apparatus is enlarged in size. In this connection, a technology for minimizing a volume of the waste ink absorbing substance by utilizing vaporization of ink is disclosed on an official gazette of Japanese Patent Application Laid-Open No. 22065/1982.

On the other hand, in the case that an image has insufficient water resistibility or a color image is formed on a printing medium that is called a plain paper with the aforementioned apparatus having an ink jet printing method applied thereto, a request for an image having a high density without an occurrence of feathering and a request for an image having no oozing of coloring substance among colors can not exist together, resulting in a quality of colored image being remarkably degraded.

In recent years, as a method of improving water

resistibility of an image, ink containing a coloring material having resistibility against water has been put in practical use. However, since this ink does not still have sufficient water resistibility, and it  
5 is ink which is theoretically hardly dissolved in ink after drying, it has a drawback that ink is liable to cause a failure of ink ejection.

In view of the foregoing fact, a technology that transparent or translucent treatment liquid containing  
10 a coloring substance which is insoluble in a solvent adheres to a printing medium with the aid of an ink jet head directly before a printing operation is disclosed in an official gazette of Japanese Patent Application Laid-Open No. 63185/1989. However, with  
15 respect to this technology, the problem specific to the ink jet apparatus is applicable to a head for the treatment liquid, and when the treatment liquid is not ejected from the nozzle, there sometimes arises an occasion that water resistibility and a quality of  
20 image corresponding to the failure of ejection of the treatment liquid are remarkably degraded. For this reason, it is necessary that the head for the treatment liquid is equipped with recovering means in the same manner as the ink jet head.

25 Fig. 9 schematically shows by way of example the structure of a conventional ink jet apparatus which is

equipped not only with recovering means for an ink jet head but also with recovering means for a head for treatment liquid. Here, each of a plurality of ink jet cartridges 1 includes an ink tank portion. A  
5 plurality of ink jet cartridges 1 each containing treatment liquid for making coloring ink and coloring material for printing insoluble are mounted on a carriage at predetermined positions. The carriage 3 is slidably supported a shaft 4 extending in the main  
10 scanning direction, and a driving belt 5 serves to transmit the driving force of the driving motor 6 for reciprocally displacing the carriage 3. A printing medium 11 is conveyed while its printing surface is flatly restricted by a platen 12. At this time, ink  
15 jet head portions 2 of the ink jet cartridges 1 mounted on the carriage 3 is projected downward of the carriage 3 to assume a position between two sets of conveying rollers (not shown) of the printing medium 11, and ink ejecting port forming surfaces of the ink  
20 jet head portions 2 faces to the printing medium 11 which is located in parallel thereto while comes in pressure contact with the guide surface of the platen 12. In addition, a recovering system unit 100 is arranged on the home position side located on the  
25 right-hand side in Fig. 9. A plurality of cap units 101 are arranged in the recovering system unit 100

corresponding to the respective ink jet head portions 2 of a plurality of ink jet cartridges 101. The cap units 101 can be raised and lowered in the vertical direction. When the carriage 3 is located at the home position, it is connected to the ink jet head portions 2 so as to cap the latter wherewith to prevent an occurrence of incorrect ejection due to increased viscosity or chemical fixing induced by vaporization of ink in the ink ejection port. A pump unit (not shown) is disposed in the recovering system unit 100. This pump unit serves to generate negative pressure when suction recovering treatment is conducted by connecting the cap unit 101 to the ink jet head portions 2. As the suction recovering treatment is conducted, the ink and the treatment liquid sucked from the ink jet head is absorbed in a waste liquid absorbing substance 103 via a tube 102 by driving the pump unit.

When suction recovering treatment is conducted with the ink jet apparatus as mentioned above, two kinds of materials, i.e, the treatment liquid and ink are present in the waste liquid absorbed in the waste liquid absorbing substance 103. However, when these two kinds of waste liquids are mixed with each other, the mixture has a nature that viscosity is increased. Thus, there arise the following problems.

(1) When both liquids are absorbed in a single waste liquid absorbing substance for the purpose of saving a space, increased viscosity or setting is caused with the result that it becomes difficult to  
5 absorb waste liquid in the whole waste liquid absorbing substance, and moreover, it is impossible to absorb the waste liquid at a high efficiency.

(2) When absorbing substances are provided separately for ink and treatment liquid so as to avoid  
10 increased viscosity of the waste liquid, cost is increased and an apparatus is enlarged in size. In addition, a replacement frequency is twice increased when the absorbing substance is saturated with the waste liquid.

15

#### OBJECT OF THE INVENTION

An object of the present invention is to provide an ink jet apparatus which improves the drawbacks  
20 inherent to the prior art and realizes an ink jet apparatus which includes a waste liquid absorbing substance in which waste liquid can effectively be held in the case that ink and waste liquid having setting/increased viscosity after completion of  
25 reaction are absorbed in a single waste liquid absorbing body substance.

## SUMMARY OF THE INVENTION

According to one aspect of the present invention,  
5 there is provided an ink jet apparatus for pretreating  
to a printing medium with treatment liquid having a  
function of setting ink by using a first ink jet head,  
and for printing on the printing medium with ink by  
using a second ink jet head, wherein the apparatus  
10 comprises first recovering means for recovering an  
ejecting port of the first ink jet head, second  
recovering means for recovering an ejecting port of  
the second ink jet head, a waste liquid absorbing  
substance for absorbing waste liquid discharged from  
15 the first recovering means and the second recovering  
means, first waste liquid transferring means for  
transferring the waste liquid discharged from the  
first recovering means the waste liquid absorbing  
substance, and second waste liquid transferring means  
20 for transferring the waste liquid discharged from the  
second recovering means into the waste liquid  
absorbing substance, wherein a discharge end of the  
first waste liquid displacing means is located in  
vicinity of one end of the waste liquid absorbing  
25 substance, and a discharge end of the second waste  
liquid displacing means is located in vicinity of

other end of the waste liquid absorbing substance.

It is acceptable that the waste liquid absorbing substance is formed in a U-shaped configuration, the discharge end of the first waste liquid displacing means is located in vicinity of one end of the U-shaped configuration, and the discharge end of the second waste liquid displacing means is located in the vicinity of other end of the U-shaped configuration of the waste liquid absorbing substance. It is also acceptable that the treatment liquid contains low molecular weight and high molecular weight cationic materials, while the ink contains an anionic dye or contains at least anionic compound and pigment. In addition, the ink jet head includes as an energy generating element an electrothermal transducer for generating thermal energy so as to allow a phenomenon of film boiling to appear in ink.

According to other aspect of the present invention, there is provided a waste liquid absorbing method for an apparatus for performing a printing operation by utilizing a treatment liquid having a function for setting ink as well as an ink, the apparatus including a waste liquid absorbing substance for absorbing the treatment liquid and the ink as waste liquid, wherein the treatment liquid and the ink are respectively absorbed in vicinity of the opposite

ends of the waste liquid absorbing substance.

It is acceptable that the waste ink absorbing substance is formed in the U-shaped configuration, and the treatment liquid and the ink are absorbed in  
5 vicinity of the opposite ends of the waste liquid absorbing substance.

With the ink jet apparatus constructed in that way, since absorbing ends are separated in a single waste liquid absorbing substance so as not to allow  
10 both the waste liquids to be mixed with each other without an occurrence of chemical fixing, it is possible to elevate an absorbing efficiency, and minimize a volume of the waste liquid absorbing substance, and moreover, construct the apparatus  
15 compactly. Consequently, the apparatus can be constructed with smaller dimensions at a reduced cost. In addition, there is no need of replacing the waste liquid absorbing substance with another one or the number of times of replacing the waste liquid  
20 absorbing substance with another one can be reduced.

The above and other objects, effects, features and advantages of the present invention will become more apparent from the following description of embodiments thereof taken in conjunction with the accompanying  
25 drawings.

## BRIEF DESCRIPTION OF THE DRAWINGS

#### DESCRIPTION OF THE PREFERRED EMBODIMENTS

5

The present invention will be described in detail hereinafter with reference to the accompanying drawings which illustrate two preferred embodiments thereof.

10 The present invention will be described below in detail with respect to two embodiments.

As shown in Fig. 1 which schematically shows by way of front view the structure of an ink jet apparatus constructed in accordance with a first  
15 embodiment of the present invention and Fig. 2 which shows the side view of the ink jet apparatus, each of a plurality of ink cartridges 1 includes upper ink tank portions and lower ink jet head portions 2 and further includes a connector (not shown) which receive  
20 a signal for driving an ink jet head. A carriage 3 carries a plurality of ink jet cartridges 1 in positions and includes a connector holder (not shown) for transmitting signals for driving an ink jet head and is electrically connected to the ink jet head. In  
25 this embodiment, a plurality of cartridges containing yellow ink, magenta ink, cyan ink and black ink

respectively and a cartridge containing treatment liquid for making coloring material insoluble are mounted on the carriage 3 in order from the right to the left. The carriage 3 is slidably supported on a guide shaft 4 extending in the main scanning direction, and a driving belt 5 serves to transmit the driving force of a driving motor 6 for reciprocally displace the driving belt 5. Pairs of conveying rollers 7, 8, 9 and 10 for conveying a printing medium 11 while the latter is clamped are arranged before and behind the printing position of the ink jet head. The printing medium 11 is conveyed while it is brought in pressure contact with a platen 12 for restricting the printing surface in the flattened state. At this time, the ink jet head portions 2 of the ink jet cartridges 1 mounted on the carriage 3 are projected downward of the carriage 3 and are located between conveying rollers 7 and 9 for conveying the printing medium 11, and ink ejecting port forming surfaces of the ink jet head portions 2 face to the printing medium 11 in the parallel state which is brought in pressure contact with the guide surface of the platen 12.

In the ink jet apparatus constructed in accordance with this embodiment, a recovering system unit 13 is arranged on the home position side located on the

right-hand side as seen in Fig. 1. A plurality of cap units 14 are arranged corresponding to the ink jet head portions 2 of a plurality of ink jet cartridges 1, and the cap units 14 can be raised and lowered in vertical direction. When the carriage 3 is located at the home position, each of cap units 14 is connected to the ink jet head portions 2 in order to prevent an occurrence of incorrect ejection due to increased viscosity and evaporation of the ink in an ink ejecting port of the ink jet head.

In addition, a pump unit (not shown) is disposed in the recovering system unit 13. When the ink jet head performs incorrect ejection, this pump unit induces negative pressure at the time of suction recovering treatment performed while the cap units 14 are connected to the ink jet head portions 2. During such suction recovering treatment, the ink sucked in the ink jet head is absorbed in a waste liquid absorbing substance 16 via a tube 15 which serves as waste liquid conveying means from the pump unit. In this embodiment, the cap for capping the treatment liquid head arranged at the left end of the recovering system unit 13 does not connect to the pump unit.

On the other hand, in this embodiment, a treatment liquid recovering unit 17 exclusively for the cartridge having the treatment liquid received therein

is disposed on the left-hand side as seen in Fig. 1 so that suction recovering treatment can be performed when the treatment liquid <sup>ejection head 29</sup>~~ejection head~~ can not correctly eject. A pump unit (not shown) is disposed also in the treatment liquid recovering system unit 17 in the same manner as the recovering system unit 13 so as to conduct suction recovering treatment in the case that the treatment liquid head does not correctly eject. The treatment liquid discharged from the treatment liquid ejection head by such recovering treatment is absorbed in the waste liquid absorbing substance 16 via a tube 18 serving as waste liquid conveying means. The reason why the treatment liquid recovering system unit 17 is separated from the recovering system unit 13 is to avoid an occurrence of incorrect suction due to increased viscosity induced by mixing the ink and treatment liquid with each other in the pump.

As described above, in this embodiment, the discharge ends of the discharge tubes 15 and 18 for discharging waste liquids from the recovering units 13 and 17 are disposed on the opposite ends of the waste liquid absorbing substance 16 which linearly extends in the leftward/rightward direction as seen in the drawings. A manner that the waste liquid is absorbed in the waste liquid absorbing substance will be

described as follows.

Fig. 3 and Fig. 4 show a manner that the waste liquid is absorbed in the waste liquid absorbing substance 16 in accordance with this embodiment.

5 Especially, Fig. 3 shows that the waste liquid absorbing substance 16 has still allowance in capacity and Fig. 4 shows that the waste liquid absorbing substance 16 is substantially saturated with waste liquids.

10 In the state as shown in Fig. 3, ink waste liquid 21 and treatment liquid waste liquid 22 absorbed in the waste liquid absorbing substance 16 through the tubes 15 and 18 are separately stored in the opposite end ranges of the waste liquid absorbing substance 16.  
15 For this reason, it can be considered that two kinds of waste liquids are absorbed in separate waste liquid absorbing substances. In this case, since the two waste liquids do not interfere with each other, there is no danger that a malfunction of increased viscosity  
20 or setting occurs. Thus, waste liquid is absorbed in the waste liquid absorbing substance 16 without any obstruction.

On the other hand, in the state shown in Fig. 4, the waste liquid absorbing substance 16 is  
25 substantially saturated with two kinds of waste liquids 21 and 22, and a jelly-like reaction product

23 is formed at the substantial central part of the waste liquid absorbing substance 16. However, since the waste liquid absorbing substance 16 is substantially saturated with the waste liquids, the  
5 jelly-like reaction product 23 does not become obstruction for the waste liquid absorption.

A balance between a quantity of waste liquid of treatment liquid and a quantity of waste liquid of ink varies due to various factors such as humidity,  
10 temperature, printing frequency or the like, and since the position where both liquids mix with each other is automatically regulated even when the foregoing balance is largely deviated from the neutral state, absorption can be achieved with the use of the whole  
15 volume of the waste liquid absorbing substance 16. Thus, the volume of the waste liquid absorbing substance 16 can be minimized, resulting in a fabrication cost being reduced. In addition, since the waste liquid absorbing efficiency is increased,  
20 there is no need of exchanging the waste liquid absorbing substance 16 with another one or there is few frequency of exchanging it with another one.

Since the ink jet apparatus having the treatment liquids used therefor is constructed in the above-  
25 described manner, the volume of the waste liquid absorbing substance 16 can effectively be utilized

with simple structure and at a low cost, whereby a high quality of image can be obtained without any undesirable increased cost.

In this embodiment, the waste liquid absorbing substance 16 extends by a long stance in the horizontal direction and the waste liquids are absorbed at the opposite ends of the waste liquid absorbing substance 16. Otherwise, the waste liquid absorbing substance 16 may extend by a long distance in the vertical direction so that the waste liquids are absorbed at upper and lower ends of the waste liquid absorbing substance 16. Alternatively, the waste liquid absorbing substrate may be designed in a cubic configuration so that the waste liquids are absorbed at the opposite diametrical ends of the waste ink absorbing substance 16.

Here, as an example, the colorless treatment liquid for making ink dyestuff insoluble can be obtained in the following manner.

Specifically, after the following components are mixed together and dissolved, and the mixture is pressure-filtered by using a membrane filter of 0.22  $\mu\text{m}$  in pore size (tradename: fuloropore filter manufactured by Sumitomo Denki Kogyo K. K.), and thereafter, pH of the mixture is adjusted to a level of 4.8 by adding sodium hydroxide whereby colorless

20 black 2.

According to the present invention, the  
aforementioned colorless liquid and ink are mixed with  
each other at the position on the printing medium or  
at the position where they penetrate in the printing  
25 medium. As a result, the ingredient having a low  
molecular weight among the cationic material contained

in the colorless liquid and the water soluble dye used in the ink having anionic radical are associated with each other by an ionic mutual function as a first stage of reaction whereby they are instantaneously  
5 separated from the solution liquid phase.

Next, since the associated material of the dyestuff and the cationic material having a low molecular weight are adsorbed by the ingredient having a high molecular weight and contained in the colorless  
10 liquid as a second stage of reaction, a size of the aggregated material of the dyestuff caused by the association is further increased, causing the aggregated material to hardly enter fibers of the printed material. As a result, only the liquid  
15 portion separated from the solid portion permeates into the printed paper, whereby both high print quality and a quick fixing property are obtained. At the same time, the aggregated material formed by the ingredient having a low molecular weight of the  
20 cationic material caused by way of the aforementioned mechanism, the anionic dye and the cationic material has increased viscosity. Thus, since the aggregated material does not move as the liquid medium moves, ink dots adjacent to each other are formed by inks each  
25 having a different color like at the time of forming a full colored image but they are not mixed with each

other. Consequently, a malfunction such as bleeding does not occur. Furthermore, since the aggregated material is substantially water-insoluble, water resistibility of a formed image is complete. In  
5 addition, light resistibility of the formed image can be improved by the shielding effect of polymer.

When the present invention is carried out, since there is no need of using the cationic material having a high molecular weight and polyvalent metallic salts  
10 like the prior art or even though there is need of using them, it is sufficient that they are assistantly used to improve an effect of the present invention, a quantity of usage of them can be minimized. As a result, the fact that there is no reduction of a  
15 property of color exhibition that is a problem in the case that an effect of water resistibility is asked for by using the conventional cationic high molecular weight material and the polyvalent metallic salts can be noted as another effect of the present invention.

20 With respect to a printing medium usable for carrying out the present invention, there is no specific restriction, so called plain paper such as copying paper, bond paper or the like conventionally used can preferably be used. Of course, coated paper  
25 specially prepared for ink jet printing and OHP transparent film are preferably used. In addition,

ordinary high quality paper and bright coated paper can preferably be used.

Ink usable for carrying out the present invention should not be limited only to dyestuff ink, and  
5 pigment ink having pigment dispersed therein can also be used. Any type of treatment liquid can be used, provided that pigment is aggregated with it. The following pigment ink can be noted as an example of  
10 pigment ink adapted to cause aggregation by mixing with the colorless liquid A1. As mentioned below, yellow ink Y2, magenta ink M2, cyan ink C2 and black ink K2 each containing pigment and anionic compound can be obtained.

[Black ink K2]

15 The following materials are poured in a batch type vertical sand mill (manufactured by Aimex Co.), glass beads each having a diameter of 1 mm is filled as media using anion based high molecular weight material P-1 (aqueous solution containing a solid ingredient of  
20 styrene methacrylic acid ethylacrylate of 20 % having an acid value of 400 and average molecular weight of 6000, neutralizing agent : potassium hydroxide) as dispersing agent to conduct dispersion treatment for 3 hours while water cooling the sand mill. After  
25 completion of dispersion, the resultant mixture has a viscosity of 9 cps and pH of 10.0. The dispersing

liquid is poured in a centrifugal separator to remove coarse particles, and carbon black dispersing element having an average grain size is 10 nm is produced.

(Composition of carbon black dispersing element)

- |    |   |           |
|----|---|-----------|
| 5  | • P-1 aqueous solution (solid ingredient of 20 %)     |           |
|    |   | 40 parts  |
|    | • carbon black (Mogul L; manufactured by Cablack Co.) | 24 parts  |
|    | • glycerol  | 15 parts  |
| 10 | • ethylene glycol monobutyl ether                     | 0.5 parts |
|    | • isopropyl alcohol                                   | 3 parts   |
|    | • water   | 135 parts |

Next, the thus obtained dispersing element is  
15 sufficiently dispersed in water, and black ink K2 containing pigment for ink jet printing is obtained. The final product has a solid ingredient of about 10 %.

[Yellow ink Y2]

- 20 Anionic high molecular P-2 (aqueous solution containing a solid ingredient of 20 % of stylen acrylic acid methyl methacrylate having an acid value of 280 and an average molecular weight of 11,000, neutralizing agent : diethanolamine) is used  
25 as a dispersing agent and dispersive treatment is conducted in the same manner as production of the

black ink K2 whereby yellow color dispersing element having an average granular diameter 103 nm is produced.

(composition of yellow dispersant)

- |    |  |           |
|----|--|-----------|
| 5  | • P-2 aqueous solution (having a solid ingredient of 20 %)                                 | 35 parts  |
|    | • C. I. pigment yellow 180<br>(tradename : Nobapalm yellow-PH-G, manufactured by Hext Co.) | 24 parts  |
| 10 | • triethylen glycol  | 10 parts  |
|    | • diethylenglycol  | 10 parts  |
|    | • ethylene glycol monobutylether   | 1.0 parts |
|    | • isopropyl alcohol  | 0.5 parts |
|    | • water  | 135 parts |

- 15 The thus obtained yellow dispersing element is sufficiently dispersed in water to obtain yellow ink Y2 for ink jet printing and having pigment contained therein. The final product of ink contains a solid ingredient of about 10 %.

20 [Cyan ink C2]

- Cyan colored-dispersant element having an average grain size of 120 nm is produced using anionic high molecular P-1 as dispersing agent, and moreover, using the following materials by conducting dispersing
- 25 treatment in the same manner as the carbon black dispersing element.

(composition of cyan colored-dispersing element)

- P-1 aqueous solution (having solid ingredient of 20 %) 30 parts
- C. I. pigment blue 15 : 3
- 5 (trade name : Fastogen blue FGF, manufactured by Dainippon Ink Kagaku Kogyo Co.) 24 parts
- glycerol 15 parts
- diethyleneglycol monobutylether 0.5 parts
- isopropyl alcohol 3 parts
- 10 • water 135 parts

The thus obtained cyan colored dispersing element is sufficiently stirred to obtain cyan ink C2 for ink jet printing and having pigment contained therein.

- 15 The final product of ink has a solid ingredient of about 9.6 %.

[Magenta ink M2]

- 20 Magenta color dispersing element having an average grain size of 115 nm is produced by using the anionic high molecular P-1 used when producing the black ink K2 as dispersing agent, and moreover, using the following materials in the same manner as that in the case of the carbon black dispersing agent.

(composition of the magenta colored dispersing  
25 element)

- P-1 aqueous solution (having a solid ingredient

|   |  |           |
|---|--|-----------|
|   | of 20 %)   | 20 parts  |
|   | • C. I. pigment red 122 (manufactured by Dainippon Ink Kagaku Kogyo Co.) | 24 parts  |
|   | • glycerol   | 15 parts  |
| 5 | • isopropyl alcohol  | 3 parts   |
|   | • water  | 135 parts |

Magenta ink M2 for ink jet printing and having  
 pigment contained therein is obtained by sufficiently  
 10 dispersing the magenta colored dispersing element in  
 water. The final product of ink has a solid  
 ingredient of about 9.2 %.

Next, description will be made below with respect  
 to an ink jet apparatus constructed in accordance with  
 15 a second embodiment of the present invention.

As shown in Fig. 5 which schematically shows the  
 front contour of the ink jet apparatus constructed in  
 accordance with the second embodiment of the present  
 invention and Fig. 6 which schematically shows the  
 20 contour of the ink jet apparatus as seen from the  
 above, a carriage having a plurality of ink jet  
 cartridges mounted thereon and associated components,  
 an ink jet head and a conveying system are same as  
 those in the first embodiment of the present  
 25 invention. Thus, same components are represented by

same reference numerals, and description on these components will be herein omitted for the purpose of simplification. Incidentally, the carriage and associated components and the paper conveyance system are not shown in Fig. 6 that is a plan view of the ink jet printing apparatus.

In this embodiment, a recovering unit 13 is disposed on the home position side located at a predetermined right-hand position as shown in Fig. 5. In the recovering unit 13, a plurality of cap units 14 are disposed corresponding to respective ink jet head portions 2 of a plurality of ink jet cartridges 1, and the cap units 14 can be raised and lowered in the vertical direction. The cap head units 14 are connected to ink jet head portions 2 to cap the latter therewith when the carriage 3 is situated at a home position, in order to prevent an occurrence of incorrect ejection due to increased viscosity of ink and setting induced by vaporization of the ink in ink ejection ports.

The recovering unit 13 is equipped with a pump unit (not shown). This pump unit serves to generate negative pressure for suction recovering treatment to be conducted while the cap units 14 are connected to the ink jet head portions 2 in the case that the ink jet head portions 2 become to incorrectly eject ink.

During suction recovering treatment, ink from the ink jet head is absorbed in a waste liquid absorbing substance 16A from the pump unit via a tube 15.

On the other hand, in this embodiment, a treatment liquid recovering system unit 17 disposed exclusively for a cartridge having treatment liquid received therein is arranged between the recovering system unit 13 and the waste liquid absorbing substance 16A. The treatment liquid recovering system unit 17 is equipped with a pump unit (not shown) like the recovering system unit 13 so as to conduct suction recovering treatment in the case that a treatment liquid ejecting head becomes to incorrectly eject treatment liquid. By conducting the recovering treatment, the treatment liquid ejected from the head is absorbed in the waste liquid absorbing substance 16A via a tube 18. The reason why the treatment liquid recovering system unit 17 is arranged separate from the recovering system unit 13 is to avoid an occurrence of incorrect suction of the pump unit due to increased viscosity induced by mixing ink with the treatment liquid in the pump.

A characterizing feature of this embodiment consists in arrangement of the waste liquid absorbing substance 16A in a U-shaped configuration as shown in Fig. 6 that is a plan view of the ink jet apparatus. The opposite ends of the U-shaped waste liquid

absorbing substance 16A are located on the right-hand side as seen in the drawing, and a discharge end of the ink tube 15 is inserted in one end of the U-shaped waste liquid absorbing substance 16A while a discharge  
5 end of a treatment liquid tube 18 is inserted into other end of the same. A boundary rib member 19 is fitted into an inner hollow portion of the U-shaped configuration of the waste liquid absorbing substance 16A so that ink absorbed in one end do not permeate to  
10 the other end across the rib member 19.

Next, a manner of permeation into the waste liquid absorbing substance 16A in accordance with this second embodiment will be described below.

Fig. 7 and Fig. 8 show how the waste liquid is  
15 absorbed in the waste liquid absorbing substance 16A. Particularly, Fig. 7 shows the state that the waste liquid absorbing substance 16A has some allowance in capacity, and Fig. 8 shows that the waste liquid absorbing substance 16A is substantially saturated  
20 with the waste liquids.

In the state as shown in Fig. 7, ink waste liquid 21 and treatment waste liquid 22 absorbed in the waste liquid absorbing substance 16A past the tubes 15 and 18 are separately stored at the opposite ends of the  
25 U-shaped waste liquid absorbing substances 16A. Thus, it can be considered that two kinds of waste liquids

are absorbed in separate waste liquid absorbing substances. Since two waste liquids do not interfere with each other, there does not arise a malfunction associated with increased viscosity or setting.

- 5 Consequently, there is not a factor of obstructing absorption of the waste liquid.

On the other hand, in the state shown in Fig. 8, the waste liquid substance 16A is substantially saturated with two kinds of waste liquids, and a  
10 jelly-like reaction product 23 formed by reaction of the two waste liquids is located at the central part of the U-shaped configuration of the waste liquid absorbing substance 16A. Since the waste liquid absorbing substance 16A is already saturated, the  
15 jelly-like reaction product 23 does not obstruct absorption of the waste liquids.

A balance between a quantity of waste treatment liquid and a quantity of waste ink varies depending on various factors such as humidity, temperature,  
20 frequency of printing operations. However, since the position where both liquids mix with each other is automatically adjusted even when the balance between the waste ink and the waste liquid is largely deviated from the neutral state, both the waste liquids can be  
25 absorbed in the whole volume of the waste liquid absorbing substance 16A. Thus, the volume of the

waste liquid absorbing substance 16A can be minimized, resulting in the cost of the apparatus being reduced. In addition, since the absorbing efficiency of the waste liquids is increased, there is no need of  
5 replacing the waste liquid absorbing substance 16A with another one or a frequency of replacing the waste liquid absorbing substance 16A with another one is few.

Additionally, in this embodiment, it is possible  
10 to accommodate two pumps for ink and pretreatment liquid in a single recovering unit, it is possible to fabricate the apparatus at a reduced cost, and moreover, it is possible to design the apparatus with smaller dimensions as seen in the direction of a  
15 width. The gap of the U-shaped portion of the waste liquid absorbing substance 16A can easily be formed by press molding. Since a rib member 19 can easily be disposed for an outer case serving also as an accommodating case for the waste liquid absorbing  
20 substance 16A by employing an integral molding process, there is not substantially any factor for producing the apparatus at an increased cost.

As mentioned above, in this embodiment, in addition to an advantages as mentioned with respect to  
25 the first embodiment, the apparatus can be designed with smaller dimensions, and moreover, the apparatus

can be produced at more reduced cost.

In this embodiment, the waste liquid absorbing substance 16A having a U-shaped configuration is formed in the horizontal direction. Alternatively, 5 the U-shaped configuration of the waste liquid absorbing substance 16A may be formed in the vertical direction so that the waste liquids are absorbed in the waste liquid absorbing substance 16A from the opposite ends of the U-shaped configuration.

10 The present invention has been described in detail with respect to preferred embodiments, and it will be now be that changes and modifications may be made without departing from the invention in its broader aspects, and it is the intention, therefore, in the 15 appended claims to cover all such changes and modifications as fall within the true spirit of the invention.
